

Orchestrator decision logic

The VLA executes only GRASP(target), LIFT, and PLACE; the controller sequences prompts from privileged simulator state.

Physical success checks

GRASP: centred closed grip plus projected contact force on both fingertips for 10 consecutive frames.

LIFT: active orange remains held and rises at least 0.06 m above its initial height for 10 consecutive frames.

PLACE: active orange is inside the oriented plate bounds, stable for 10 frames, and released with the gripper open.

A GRASP timeout triggers a home-pose reset before reselection; LIFT/PLACE failures preserve the same target.
